Inhalt

Überblick
I. Objektorientierung und Erweiterbarkeit
1. Benutzerdefinierte Datentypen und getypte Tabellen
2. Objekt-relationale Sichten und Kollektionstypen
3. Benutzerdefinierte Routinen und Objektverhalten
4. Anbindung an Anwendungsprogramme
5. Objekt-relacionales SQL und Java
II. Online Analytic Processing
6. Datenanalyse in SQL
7. Windows und Query Functions
III. XML
8. XML und Datenbanken
9. SQL/XML
10. XQuery
Neuere Entwicklungen für Datenmodelle und Anfragesprachen

The "Big Picture"

Client
- dynamic SQL
  - JDBC 2.0
- static SQL
  - SQL DB ANSI
  - ISO

DB Server
- SQL99
- SQL92
- stored procedures
- user-defined functions
- advanced datatypes
- structured types
- subtyping
- methods

Server-side Logic
- SQLJ Part 1
  - SQL Routines
  - PSM
  - External Routines
- SQLJ Part 2

User-defined Types: Key Features

- New functionality
  - Users can indefinitely increase the set of provided types
  - Users can indefinitely increase the set of operations on types and extend SQL to automate complex operations/calculations
- Flexibility
  - Users can specify any semantics and behavior for a new type
- Consistency
  - Strong typing insures that functions are applied on correct types
- Encapsulation
  - Applications do not depend on the internal representation of the type
- Performance
  - Potential to integrate types and functions into the DBMS as "first class citizens"
### User-defined Types: Benefits

- Simplified application development
  - Code Re-use - allows reuse of common code
  - Overloading and overriding - makes application development easier -- single function name for a set of operations on different types, e.g., area of circles, triangles, and rectangles
- Consistency
  - Enables definition of standard, reusable code shared by all applications (guarantee consistency across all applications using type/function)
- Easier application maintenance
  - Changes are isolated: if application model changes, only the corresponding types/functions need to change instead of code in each application program

### User-defined Distinct Types

- Before SQL99, columns could only be defined with the existing built-in data types
  - There was no strong typing
  - Logically incompatible variables could be assigned to each other

```sql
CREATE TABLE RoomTable (
    RoomID CHAR(10),
    RoomLength INTEGER,
    RoomWidth INTEGER,
    RoomArea INTEGER,
    RoomPerimeter INTEGER);
```

```sql
UPDATE RoomTable
SET RoomArea = RoomLength;
No Error Results
```
User-defined Distinct Types

- Each UDT is logically incompatible with all other types

```sql
CREATE TYPE plan.roomtype
    AS CHAR(10) FINAL;
CREATE TYPE plan.meters
    AS INTEGER FINAL;
CREATE TYPE plan.squaremeters
    AS INTEGER FINAL;
CREATE TABLE RoomTable (RoomID plan.roomtype,
    RoomLength plan.meters,
    RoomWidth plan.meters,
    RoomPerimeter plan.meters,
    RoomArea plan.squaremeters);
```

```sql
UPDATE RoomTable
SET RoomArea = RoomLength;
ERROR
UPDATE RoomTable
SET RoomLength = RoomWidth;
NO ERROR RESULTS
```

User-defined Distinct Types

- Based on name equivalence (strongly typed)
  - Renamed type, with different behavior than its source type.
    - Shares internal representation with its source type
    - Source and distinct type are not directly comparable

```sql
CREATE TYPE US_DOLLAR AS DECIMAL (9,2) FINAL
```

- Operations defined on distinct types (behavior)
  - Comparison/ordering
    - Can be based on the comparison/ordering of their source type
  - Casting
    - Used to explicitly cast instances of the distinct type and instances of source type to and from one another
    - Used to obtain "literals"
  - Methods and functions
  - No inheritance or subtyping
Cast Functions for Distinct Types

- Automatically defines cast functions to and from the source type for a user-defined distinct type
- Casts will also be allowed from any type that is promotable to the source type of the user-defined type (i.e., that has the source type in its type precedence list)
- Casting from a SMALLINT to a UDT sourced on an integer is OK

```
CREATE TYPE plan.meters
AS INTEGER FINAL
CAST (SOURCE AS DISTINCT) WITH meters
CAST (DISTINCT AS SOURCE) WITH integer

Implicit Cast Functions created:
  plan.meters(integer) returns meters;
  plan.integer(meters) returns integer;
```

Example Casting Expressions:

- SET RoomWidth = CAST (integerCol AS meters)
- meters(integerCol)
- meters(smallintCol)

Cast Functions: Comparison Rules

- Casts must be used to compare distinct type values with source-type values.
- Constants are always considered to be source type values
- You may cast from source type to UDT, or vice-versa

```
SELECT * FROM RoomTable
WHERE RoomID = 'Bedroom';
ERROR
SELECT * FROM RoomTable
WHERE RoomID = roomtype('Bedroom');
or
SELECT * FROM RoomTable
WHERE char(RoomID) = 'Bedroom';
No Error Results
```
Cast Functions: Assignment Rules

- In general source-type values may not be assigned to user-defined type targets.
- The strong typing associated with UDTs is relaxed for assignment operations, IF AND ONLY IF:
  - A cast function between source and target type has been defined with the AS ASSIGNMENT clause.

```
CREATE TYPE plan.meters
AS INTEGER FINAL
CAST (SOURCE AS DISTINCT) WITH meters
CAST (DISTINCT AS SOURCE) WITH integer
CREATE CAST (plan.meters AS integer) WITH integer AS ASSIGNMENT
CREATE CAST (integer AS plan.meters) WITH meters AS ASSIGNMENT
```

Distinct Types vs. Domains

- Domains in SQL:
  - domain definition
    - name
    - data type (similar to source type)
    - constraint (optional)
    - default (optional)
    - collation (optional)
  - comparable to macros in programming languages
    - no notion of strong typing
  - casting
    - if the target is a domain that has a domain constraint, then the constraint has to be satisfied
- Warning: other definitions for the term "domain" exist!
  - see, e.g., Date/Darwen "Foundation for Object/Relational Databases"
  - "domain" and "type" used interchangeably
User-defined Structured Types

- User-defined, complex data types
  - Can be used as column types and/or table types
- Column Types
  - E.g., text, image, audio, video, time series, point, line, ...
  - For modeling new kinds of facts about enterprise entities
  - Enhanced infrastructure for SQL/MM
- Row Types
  - Types and functions for rows of tables
    - E.g., employees, departments, universities, students, ...
    - For modeling entities with relationships & behavior
  - Enhanced infrastructure for business objects

```
CREATE TYPE employee AS
(id INTEGER,
 name VARCHAR (20))
```

Structured Types: Example

```
CREATE TYPE address AS
(street CHAR (30),
city CHAR (20),
state CHAR (2),
zip INTEGER) NOT FINAL

CREATE TYPE bitmap AS BLOB FINAL

CREATE TYPE real_estate AS
(owner REF (person),
price money,
rooms INTEGER, 
size DECIMAL(8,2),
location address, 
text_description text, 
front_view_image bitmap,
document doc) NOT FINAL
```
Use of Structured Types

- Wherever other (predefined data) types can be used in SQL
  - Type of attributes of other structured types
    ```sql
    CREATE TYPE address AS (street CHAR (30), ...) NOT FINAL
    CREATE TYPE real_estate AS (... location address, ...) NOT FINAL
    ```
  - Type of parameters of functions, methods, and procedures
  - Type of SQL variables
  - Type of domains or columns in tables

- To define tables and views
  ```sql
  CREATE TABLE properties OF real_estate ...
  ```

Creating Structured Types

- System-supplied constructor function
  ```sql
  address () -> address or real_estate () -> real_estate
  ```
  - Returns new instance with attributes initialized to their default

- NEW operator
  ```sql
  NEW <type name>
  ```
  - Invokes constructor function

- INSERT statement against a table
  ```sql
  CREATE TABLE properties ...
  INSERT INTO properties
  VALUES (:owner, money (350000), 15, 4500, NEW address, ...)
  ```
Manipulating Attributes

- **Observer** and **mutator** methods are used to access and modify attributes
  - Automatically generated when type is defined
    ```sql
    CREATE TYPE address AS (street CHAR (30), city CHAR (20), state CHAR (2), zip INTEGER) NOT FINAL
    ```
    ```sql
    address_expression.street () -> CHAR (30)
    address_expression.city () -> CHAR (20)
    address_expression.state () -> CHAR (2)
    address_expression.zip () -> INTEGER
    address_expression.street (CHAR (30)) -> address
    address_expression.city (CHAR (20)) -> address
    address_expression.state (CHAR (2)) -> address
    address_expression.zip (INTEGER) -> address
    ```

Dot Notation

- "Dot" notation must be used to invoke methods (e.g., to access attributes)
- Methods without parameters do not require use of "()"
  ```sql
  SELECT location.street, location.city (), location.state, location.zip ()
  FROM properties
  WHERE price < 100000
  ```
- Support for several 'levels' of dot notation (a.b.c.d.e)
- Allow "navigational" access to structured types
- Support for "user-friendly" assignment syntax
  ```sql
  DECLARE r real_estate;
  ...
  SET r.size = 2540.50;  -- same as r.size (2540.50)
  ...
  SET ... = r.location.state;  -- same as r.location().state()
  SET r.location.city = `LA';  -- same as r.location(r.location.city(`LA'))
  ```
- Dot notation does not 'reveal' physical representation (keeps encapsulation)
Subtyping and Inheritance

- Structured types can be a subtype of another UDT
- UDTs inherit structure (attributes) and behavior (methods) from their supertypes
- Example
  - CREATE TYPE real_estate ... NOT FINAL
  - CREATE TYPE apartment UNDER real_estate ... NOT FINAL
  - CREATE TYPE house UNDER real_estate ... NOT FINAL

Noninstantiable and Final Types

- Structured types can be **noninstantiable**
  - Like abstract classes in OO languages
  - No system-supplied constructor function is generated
  - Type does not have instances of its own
  - Instances can be defined on subtypes
- By default, structured types are instantiable
- Distinct types are always instantiable
  - CREATE TYPE person AS
    (name VARCHAR (30),
    address address,
    sex CHAR (1))
    NOT INSTANTIABLE NOT FINAL
- User-defined types may be **final**
  - no subtypes can be defined
  - distinct types have to be **FINAL**
  - structured types have to be **NOT FINAL**
  - future version of SQL may introduce more flexibility
Value Substitutability

CREATE TYPE address AS
     (street CHAR(30), city CHAR(20), state CHAR(2), zip INTEGER) NOT FINAL
CREATE TYPE german_addr UNDER address
     (family_name VARCHAR(30) ) NOT FINAL
CREATE TYPE brazilian_addr UNDER address
     (neighborhood VARCHAR(30) ) NOT FINAL
CREATE TYPE us_addr UNDER address
     (area_code INTEGER, phone INTEGER) NOT FINAL
CREATE TYPE us_bus_addr UNDER us_address
     (bus_area_code INTEGER, bus_phone INTEGER) NOT FINAL

![Diagram of address types]

- Each row can have a value a different subtype

```
INSERT INTO properties (price, owner, location)
VALUES (US_dollar (100000), REF('Mr.S.White'), NEW us_addr ('1654 Heath Road', 'Heath', 'OH', 45394, ...))
```

```
INSERT INTO properties (price, owner, location)
VALUES (real (400000), REF('Mr.W.Green'), NEW brazilian_addr ('245 Cons. Xavier da Costa', 'Rio de Janeiro', 'Copacabana'))
```

```
INSERT INTO properties (price, owner, location)
VALUES (german_mark (150000), REF('Mrs.D.Black'), NEW german_addr ('305 Kurt-Schumacher Strasse', 'Kaiserslautern', 'Prof. Dr. Heuser'))
```
Type Predicate

- Allows determination of **dynamic** type (**most specific** type)
- Purpose
  - Allows row selection by specific subtypes (e.g. only with EURO in MONEY column)
    - IS OF
  - Allows to prune off certain subtypes (e.g. French Francs)
    - ONLY
- Example: Find items from properties table that are priced in EURO (but not in any of its substitutes, e.g. Dutch guilders):

```
SELECT * FROM properties
WHERE Price IS OF ONLY (EURO)
```

Structured Types as Row Types: Typed Tables

- Structured types can be used to define typed tables
  - Attributes of type become columns of table
  - In addition, a typed table has a so-called **self-referencing column**
    - holds a value that uniquely identifies the row (similar to an object id)
      - (more details later)

```
CREATE TYPE real_estate AS
(price money,
rooms INTEGER,
size DECIMAL(8,2),
location address,
text_description text,
front_view_image bitmap,
document doc) NOT FINAL ...

CREATE TABLE properties OF real_estate
(REF IS oid ...)
```
Manipulating Attributes

- Queries over type tables access attributes (columns)
- Update statements on typed tables modify attributes

```
CREATE TABLE properties OF real_estate ... 

SELECT owner, price 
FROM properties 
WHERE address = NEW address ('1543 3rd Ave. North, Sacramento, CA 93523') 

UPDATE properties 
SET price = 350000 
WHERE address = NEW address ('1543 3rd Ave. North, Sacramento, CA 93523')
```

Subtables: Table Hierarchies

- Typed tables can have subtables
  - Inherit columns, contraints, triggers, ... from the supertable
- Example
  - Given the following type hierarchy ...

```
real_estate

appartment

house

properties

appartments

houses
```

- Create a table hierarchy:
  CREATE TABLE properties OF real_estate ( ... )
  CREATE TABLE appartments OF appartment UNDER properties
  CREATE TABLE houses OF house UNDER properties
Relationship to Type Hierarchies

- Each table $T(i)$ in the hierarchy must correspond to a type $ST(i)$ of a single type hierarchy
- Relationships must match
  - $T(i)$ UNDER $T(j) => ST(i)$ UNDER $ST(j)$
- Not all types in the hierarchy have to have corresponding tables in the table hierarchy
- Multiple table hierarchies may be defined, based on the same type hierarchy

Substitutability

- Queries on table hierarchies range over the rows of every subtable
  
  ```sql
  SELECT price, location.city, location.state FROM properties
  WHERE address.city = 'Sacramento'
  
  Returns rows from properties, appartments, and houses
  
  Can only return columns defined for properties
  
  E.g., `SELECT * FROM properties` will not return attributes created in the appartment type
- Queries on a subtable require SELECT privilege on that subtable
  
  ```sql
  SELECT * FROM appartments...
  ```
Reference Types

- Structured types have a corresponding reference type
  - REF(<structured type name>)
  - used to identify/reference instances of the structured type stored in types tables
    - identifier: stored in the self-referencing column of a typed table
      - has to be unique within the table hierarchy
  - Can be used wherever other types can be used

Representation

- User generated (REF USING <predefined type>)
  - CREATE TYPE real_estate AS
    (owner REF (person), ...)
  - NOT FINAL REF USING INTEGER
- System generated (REF IS SYSTEM GENERATED)
  - Default is system generated
- Derived from a list of attributes (REF (<list of attributes>)
  - CREATE TYPE person AS
    (ssn INTEGER,
     name CHAR(30),...)
  - NOT FINAL REF (ssn)

Reference Type Representation

<table>
<thead>
<tr>
<th>self-referencing column (SRC)</th>
<th>SYSTEM GENERATED</th>
<th>USER GENERATED</th>
<th>DERIVED (c₁, ..., cn)</th>
</tr>
</thead>
<tbody>
<tr>
<td>uniqueness</td>
<td>UNIQUE, NOT NULL is implicit</td>
<td>UNIQUE, NOT NULL is implicit</td>
<td>UNIQUE, NOT NULL is implicit, (c₁, ..., cn) has to be UNIQUE, NOT NULL as well</td>
</tr>
<tr>
<td>id value generation</td>
<td>automatic</td>
<td>by user/application during INSERT</td>
<td>automatic (based on c₁, ..., cn)</td>
</tr>
<tr>
<td>id update</td>
<td>not permitted</td>
<td>not permitted</td>
<td>not permitted, but c₁, ..., cn can be updated (?)</td>
</tr>
<tr>
<td>id reuse</td>
<td>can be prohibited by the DBS</td>
<td>has to be prohibited/controlled by application</td>
<td>has to be prohibited/controlled by application</td>
</tr>
</tbody>
</table>
Reference Types

- Reference values can be scoped
  - typed table in which the referenced objects have to exist
  - the reference can be CHECKED
  - existence of referenced object is guaranteed by the DBMS
  - ON DELETE clause, similar to referential integrity constraint

Example:

CREATE TYPE person (ssn INTEGER, name ...) NOT FINAL
CREATE TYPE real_estate (owner REF (person), ...) NOT FINAL
CREATE TABLE people OF person (...)
CREATE TABLE properties OF real_estate
  (owner WITH OPTIONS SCOPE people REFERENCES ARE CHECKED)

More on Reference Types

- References are strongly typed
  - only references to the same/compatible type can be compared, assigned, ...
- References support substitutability
  - for REF(T), a reference to an instance of a subtype of T is permitted
- Inserting reference values
  - USER GENERATED
    - value is provided by the application, just like any other column/attribute value
    - appropriate CAST functions are available
  - SYSTEM GENERATED or DERIVED reference
    - value needs to be retrieved from the database (in a subquery)
**Path Expressions**

- Scoped references can be used in path expressions
  
  ```sql
  SELECT prop.price, prop.owner->name FROM properties prop
  WHERE prop.owner->address.city = "Hollywood"
  ```

- Authorization checking follows SQL authorization model
  
  - user must have SELECT privilege on people.name and people.address
  - the above statement is equivalent to
    
    ```sql
    SELECT prop.price, (SELECT name FROM people p WHERE p.oid = prop.owner)
    FROM properties prop
    WHERE (SELECT p.address.city FROM people p WHERE p.oid = owner) = "Hollywood"
    ```

  ```sql
  SELECT prop.price, p.name
  FROM properties prop LEFT JOIN people p ON (prop.owner = p.oid)
  WHERE p.address.city = "Hollywood"
  ```

**Reference Resolution: Nesting**

- References can be used to obtain the structured type value that is being referenced
  
  - Enables nesting of structured types
    
    ```sql
    SELECT prop.price, DEREF(prop.owner) AS ownerval
    FROM properties.prop
    ```
  
  - Column ownerval in the result table has static type `person`
  
  - DEREF nests rows from subtables, respecting value substitutability
    
    - most specific type of ownerval values may be a subtype of `person`
Reference Types vs. Referential Constraints

- References do not have the same semantics as referential constraints

```
CREATE TABLE T1
(C1 REAL PRIMARY KEY, ...)
CREATE TABLE T2
(C2 DECIMAL (7,2) PRIMARY KEY, ...)
CREATE TABLE T
(C INTEGER, ...
FOREIGN KEY (C) REFERENCES T1 (C1) NO ACTION,
FOREIGN KEY (C) REFERENCES T2 (C2) NO ACTION)
```

- Referential constraints specify inclusion dependencies
  - It is unclear which table to access during dereferencing
  - There is no notion of strong typing

Type Predicate and ONLY on Typed Tables

- Type predicate can be used to restrict selected rows

```
SELECT price, location.city, location.state
FROM properties
WHERE address.city = 'Sacramento'
AND DEREF (oid) IS OF (house)
```

- ONLY restricts selected rows to rows whose most specific type is the type of the typed table

```
SELECT price, location.city, location.state
FROM ONLY (properties)
WHERE address.city = 'Sacramento'
```
Comparison of UDT Values

- CREATE ORDERING statement specifies
  - Which comparison operations are allowed for a user-defined type
  - How such comparisons are to be performed.

  - CREATE ORDERING FOR employee
    EQUALS ONLY BY STATE;
  - CREATE ORDERING FOR complex
    ORDER FULL BY RELATIVE
    WITH FUNCTION complex_order (complex,complex);

- Ordering form:
  - EQUALS ONLY
    - Only comparison operations allowed are $=, <$
  - ORDER FULL
    - All comparison operations are allowed

Comparison of UDT Values (cont.)

- Ordering category
  - STATE
    - An ordering function is implicitly created with two UDT parameters and returning Boolean
    - Compares pairwise the UDT attributes
  - RELATIVE
    - User must specify an ordering function with two UDT parameters and returning INTEGER
    - 0 for equal, positive for $>$, negative for $<$
  - MAP
    - User must specify an ordering function with one UDT parameter and returning a value of a predefined type
    - Comparisons are made based on the value of the predefined type
Comparison of UDT Values (cont.)

- **Ordering category - Rules:**
  - STATE cannot be specified for distinct types.
  - STATE and RELATIVE must be specified for the maximal supertype in a type hierarchy.
  - MAP can be specified for more than one type in a type hierarchy, but all such types must specify MAP and all such types must have the same ordering form.
  - STATE is allowed only for EQUALS ONLY.
  - If ORDER FULL is specified, then RELATIVE or MAP must be specified.

Comparison of UDT Values (cont.)

- **Comparison type** of a given type:
  - The nearest supertype for which a comparison was defined.
  - Comparison form, comparison category, and comparison function of a type are the ordering form, ordering category, ordering function of its comparison type.

- A value of type T1 is **comparable** to a value of type T2 if
  - T1 and T2 are in the same subtype family.
  - Comparison types of T1 and T2 both specify the same comparison category (i.e., STATE, RELATIVE, or MAP)

- **Example**
  - Person has subtypes: emp and mgr
  - Person has an ordering form, ordering category, and an ordering function
    - emp and mgr types have none
  - Person is the comparison type of emp and mgr
  - Two emp values, two mgr values, or a value of emp and a value of mgr can be compared.
Comparison of UDT Values (cont.)

- No comparison operations are allowed on values of structured types by default.
- All comparison operations are allowed on values of distinct types by default.
  - Based on the comparison of values of source type.
  - Whenever a distinct type is created, a CREATE ORDERING statement is implicitly executed (SDT is the source type).
  - The ordering function is the system-generated cast function

```sql
CREATE ORDERING FOR DT
ORDER FULL BY MAP WITH FUNCTION SDT(DT);
```

Comparison of UDT Values (cont.)

- A predicate of the form "V1 = V2" is transformed into the following expression depending on the comparison category:
  - STATE
    - "SF(V1,V2) = TRUE"
    - SF is the comparison function
  - MAP
    - "MF1(V1) = MF2(V2)"
    - MF1 and MF2 are comparison functions
  - RELATIVE
    - "RF(V1,V2) = 0"
    - RF is the comparison function
Comparison of UDT Values (cont.)

- **DROP ORDERING**
  - Removes the ordering specification for an UDT
  
  
  DROP ORDERING FOR employee RESTRICT;

- **RESTRICT implies**
  - There cannot be any
    - SQL-invoked routine
    - View
    - Constraint
    - Assertion
    - Trigger
  - that has a predicate involving employee values or values of subtypes thereof.

User-defined Casts

- **Allow a value of one type to be cast into a value of another type**
  - At least one of the types in a user-defined cast must be a user-defined type or a reference type.
    
    CREATE CAST(t1 AS t2) WITH FUNCTION foo (t1);
    SELECT CAST(c1 AS t2) FROM TAB1;
  
  - May optionally be tagged AS ASSIGNMENT
    
    CREATE CAST(t1 AS t2) WITH FUNCTION foo (t1) AS ASSIGNMENT;
  
  - Such casts get invoked implicitly during assignment operations.
  - Above user-defined cast makes the following assignment legal:
    
    DECLARE v1 t1, v2 t2;
    SET v2 = v1;
User-defined Casts (cont.)

- **DROP CAST**
  - Removes the user-defined cast
  - Does not delete the corresponding function (only its cast flag is removed)
  
  \[
  \text{DROP CAST (T1 AS T2) RESTRICT;}
  \]

- **RESTRICT** implies:
  - There cannot be any
    - Routine
    - View
    - Constraint
    - Assertion
    - Trigger
  - that has
    - An expression of the form "CAST(V1 AS T2)" where V1 is of type T1 or any subtype of T1;
    - A DML statement that implicitly invokes the user-defined cast function.
