

# Business Processes and Web Services

## Workflows and Web Services Kapitel 10

### Introduction

- Web Services Composition
  - Ability to create new web services out of existing (web service) components
  - Requirements similar to BPM, Workflow Management
    - separate function from composition logic, ...
- Limitations of conventional composition middleware (e.g., WFMS)
  - Significant effort to integrate existing applications
    - application-specific adapters, wrappers
    - no standard model for component description, interoperability
  - Limited success of composition model standardization
    - WfMC standard is not widely implemented
- Opportunities for Web Services
  - Web Services seem to be adequate components
    - well-defined interfaces, described using WSDL
    - standardized invocation (SOAP)
  - Significant efforts in standardizing WS composition languages
  - Reuse of existing WS "infrastructure" (directory, service selection, ...)
    - WS composition tools are less expensive to develop

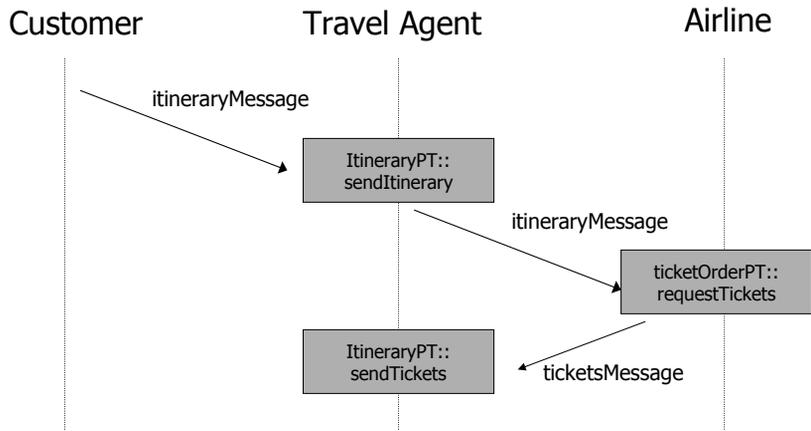

# Business Processes and Web Services

- Business Process Execution Language for Web Services (BPEL4WS)
  - XML-based language for specifying business process behavior based on web services
  - Describe business processes that both provide and consume web services
    - Steps (activities)
      - Implemented as an interaction with a web service
    - Information flow into/out of the process
      - Externalized as web service
- Complemented by
  - WS Coordination specification
    - Allows to web services involved in a process to share information that "links" them together
      - Shared coordination context
  - WS Transaction specification
    - Allows to monitor the success/failure of each coordinated activity
      - Reliably cancel the business process, involves compensating activities
- Specifications proposed by IBM, Microsoft, BEA (and Siebel for BPEL 1.1)
  - BPEL unifies XLANG (Microsoft), WSFL (IBM)
  - transferred to OASIS for standardization

# BPEL4WS

- Business process defines
  - Potential execution order of operations (web services)
  - Data shared between the web services
  - Partners involved in business process
  - Joint exception handling for collection of web services
- Long running transactions between web services
- BPEL script
  - Fully executable specification of business process
    - Portable between BPEL-conformant environments
  - Supports specification of business protocols between partners

## BPEL Example – Flow Diagram

## Partners

- Partner link definition
  - Specifies the web services mutually used by the partner or process
    - E.g., agent process interacts with customer, airline
  - References a partner link type
    - Connects a partner to a process
    - Specifies collections of web services: roles
      - Provided and required by the connected partners
  - Defines role taken by the process itself (myRole) and role that has to be accepted by the partner (partnerRole)

```

1 <process name="ticketOrder">
2 <partnerLinks>
3   <partnerLink name="customer"
4     partnerLinkType="agentLink"
5     myRole="agentService"/>
6   <partnerLink name="airline"
7     partnerLinkType="buyerLink"
8     myRole="ticketRequester"
9     partnerRole="ticketService"/>
10 </partnerLinks>
    
```

### Partner link type definition

```

1 <partnerLinkType name="buyerLink">
2   <role name="ticketRequester">
3     <portType name="itineraryPT"/>
4   </role>
5   <role name="ticketService">
6     <portType name="ticketOrderPT"/>
7   </role>
8 </partnerLinkType>
    
```

## Partners (cont.)

- Definition of partners in addition to partner links
  - optional definition
  - may require the same partner to play multiple roles
    - partner definitions must not overlap
  - Example

```
<partners>
  <partner name="SellerShipper">
    <partnerLink name="Seller"/>
    <partnerLink name="Shipper"/>
  </partner>
</partners>
```
- Partner link names are used in all service interactions to identify partners
  - see activities for invoking/providing services
- Assignment of endpoints for partners
  - at deployment time
  - dynamically at run time

## Properties

- Property
  - Globally defined types
  - Primarily used to correlate a message with a specific process instance
    - E.g., order number
    - Usually included in the message
    - Often the same property is used in different messages
  - Can be defined in BPEL as a separate entity:

```
9 <property name="orderNumber" type="xsd:int"/>
```
- Property alias
  - Allows to point to a dedicated field of the message that represents the property
    - Usually different for each message type
    - Can be used in expression and assignments to easily use properties

```
10 <propertyAlias propertyName="orderNumber"
11     messageType="ticketsMessage"
12     part="orderInfo"
13     query="/orderID"/>
```

## Correlation

- Message needs to be delivered not only to the correct port, but to the correct instance of the business process providing the port
- Correlation Set
  - one or more properties used for correlating messages
  - example
    - `<correlationSets>`
    - `<correlationSet name="Booking"`
    - `properties="orderNumber"/>`
    - ...
    - `</correlationSets>`
  - correlation properties are like "late-bound constants"
    - binding happens through specially marked message send/receive activities
    - value must not change after the binding happens
- Often, more than one correlation set is used for an entire process
  - example: orderNumber -> invoiceNumber
  - correlated message exchanges may nest, overlap
  - same message may carry multiple correlation sets

## Variables

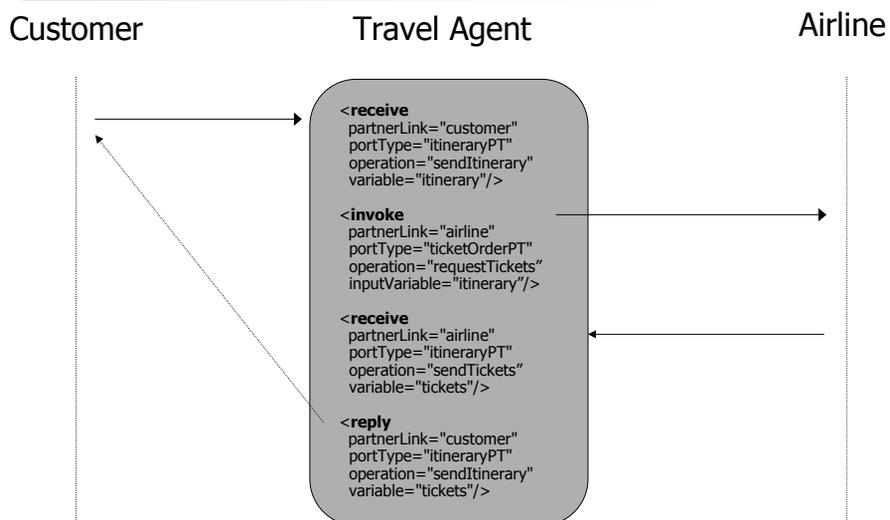

- Variables are used to define data containers
  - WSDL messages received from or sent to partners
  - Messages that are persisted by the process
  - XML data defining the process state
- Constitute the "business context" of the process
- Access to variables can be serialized to some extent
  - Serializable scopes

```
11 <variables>
12   <variable name="itinerary" messageType="itineraryMessage"/>
13   <variable name="tickets" messageType="ticketsMessage"/>
14 </variables>
```

# Activities

- Types of (simple) activities
  - Receive
    - Wait for a message to be received from a partner
    - Specifies partner from which message is to be received, as well as
    - The port and operation provided by the process
      - Used by the partner to pass the message
  - Reply
    - Synchronous response to a request corresponding to a receive activity
    - Combination of Receive/Reply corresponds to request-response operation in WSDL
  - Invoke
    - Issue an asynchronous request
    - Synchronously invoke an in-out operation of a web service provided by a partner

# Activities – Example

## More simple activities

---

- Wait
  - Process should wait for a specified time period or until a point in time
- Empty
  - No action
    - Can serve as a means to synchronize parallel processing within the process
- Terminate
  - Business process should be terminated immediately
- Throw
  - Signal occurrence of an error
- Assign
  - Copies fields from containers into other containers
- Compensate
  - Undo the effects of completed activities

## Structured activities

---

- Sequence
  - Enclosed activities are carried out in listed order
- Switch
  - Selects one of several activities based on selection criteria
- While
  - Carry out enclosed activities as long as the while condition is true
- Pick
  - Specifies a whole set of messages
    - can be received from the same or different partners
  - Activity is completed when one of the specified messages is received
  - Permits specifying a time limit after which processing continues if message is not received
  - Pick and Receive can be start activities of a process
    - Can indicate that a process instance should be created if none exists

## Flow of Activities

- Flow
  - Directed graph with
    - **Activities** as nodes
    - **Links** as edges connecting the activities
  - Each activity defines the links it is a source or a target of

```
15 <flow>
16   <links>
17     <link name="order-to-airline"/>
18     <link name="airline-to-agent"/>
19   </links>
20   <receive partnerLink="customer"
21     portType="itineraryPT"
22     operation="sendItinerary"
23     variable="itinerary">
24     <source linkName="order-to-airline"/>
25   </receive>
26   <invoke partnerLink="airline"
27     portType="ticketOrderPT"
28     operation="requestTickets"
29     inputVariable="itinerary">
30     <target linkName="order-to-airline"/>
31     <source linkName="airline-to-agent"/>
32   </invoke>
33   <receive partnerLink="airline"
34     portType="itineraryPT"
35     operation="sendTickets"
36     variable="tickets">
37     <target linkName="airline-to-agent"/>
38   </receive>
39 </flow>
40 </process>
```

## Flow Activity

- Defines sets of activities plus (optional) control flow
  - All activities can (potentially) execute in parallel
  - Activities can be "wired together" via links
    - Links used to "synchronize" them
  - Activities can again be flows
- Links can be associated with transition conditions
  - Specified at the source activity
- Target of link has join condition
  - Explicit join condition can reference the status of incoming links
  - Implicit join condition: at least one incoming link has a positive status

## Link Semantics

- Control Flow Navigation (see chapter 7)
  - Evaluation of link status, join conditions evaluated only if status of all incoming links has been evaluated
  - Dead path elimination
    - Attribute suppressJoinFailure="yes"
- Links can cross boundaries of structured activities
  - Some restrictions apply
    - must not cross while-activity, serializable scope, compensation handler, event handler
    - no links into a fault handler
  - Careful consideration of resulting semantics
- Links must not build a control cycle!

## Scope

- Defines the behavior context of an activity
  - simple or structured (group of activities)
- Can provide the following for a (regular) activity
  - (Local) data variables
  - Correlation Sets
  - Fault handler(s)
  - Event handler(s)
  - Compensation handler
    - Scope acts as a compensation sphere

## Fault Handlers

- Fault handlers catch and deal with faults
  - Process interacts with WSDL port, WSDL port may send fault message back to a process
  - Internal fault (throw activity)
- Fault reaching a fault handler means that regular processing within scope can no longer proceed
  - All active work in the scope must be stopped!
- Catch element
  - Specifies fault to be handled
  - Includes activity (simple or structured) to be performed if fault occurs

```
35 <faultHandlers>
36   <catch faultName="noSeatsAvailable">
37     <invoke partner="customer"
38           portType="travelPT"
39           operation="sendRejection"
40           inputContainer="rejection"/>
41   </catch>
42 </faultHandlers>
```
  - May make use of compensation handlers to undo completed nested activities
- After fault handler completes successfully, processing may continue outside the scope
  - Processing of the scope is still considered to have ended abnormally

## Compensation Handler

- Used to reverse the work of a **successfully completed** scope
  - compensation handler is "installed" after successful completion of the scope
- Can be defined for each scope
  - Scopes can be arbitrarily nested
  - Syntactic shortcut for invoke activity
    - Inline definition of compensation handler
    - Equivalent to scope with comp. handler and invoke activity
- Compensation activity can be any activity

## Compensation Handlers – Example

```
<scope name="purchase">
  <compensationHandler>
    <invoke partner="Seller"
      portType="SP:Purchasing"
      operation="CancelPurchase"
      inputContainer="getResponse"
      outputContainer="getConfirmation">
    </invoke>
  </compensationHandler>
  <invoke partner="Seller"
    portType="SP:Purchasing"
    operation="SyncPurchase"
    inputContainer="sendPO"
    outputContainer="getResponse">
  </invoke>
</scope>
```

## Compensation Handler Invocation

- Compensate activity
  - Invokes compensation handler for named scope
    - Example: `<compensate scope="purchase"/>`
  - Can be invoked only from the fault handler or compensation handler of the immediately enclosing scope
- Data semantics
  - When invoked, compensation handler sees frozen snapshot of data variables
    - All variables in the state they were at completion time of the scope being compensated
  - Compensation handlers live in a snapshot world
    - Cannot update "live" data variables
    - Can only affect external entities
    - Input/output parameters for compensation handler are future direction

## Default Compensation and Fault Handlers

- Default compensation handler
  - Invokes compensation handlers of immediately enclosed scopes in the reverse order of the completion of the scopes
  - Is used if a (enclosing) scope does not explicitly define a compensation handler
  - Can also be invoked explicitly
    - Useful if comp. action = "compensate enclosed scope in reverse order" + "additional activities"
- Default fault handler
  - Invokes compensation handlers of immediately enclosed scopes in the reverse order of the completion of the scopes
  - Rethrows the exception

## More on Faults

- Termination of running activities
  - Regular processing is stopped
  - If the activity is a scope, the fault handler for forcedTermination fault is invoked
    - Activity being terminated can react to termination
      - call compensation handlers of nested, completed activities, ...
    - Implicit fault handler is invoked otherwise
- Faults occurring in compensation handlers or fault handlers
  - Can be caught by regular fault handlers in enclosing scopes or scopes with the fault handler

## Process life-cycle

- Start activities
  - receive, pick – createInstance attribute
    - creates a new process instance, if it doesn't exist already
  - Example:

```
<receive partner="customer",
  portType="itineraryPT",
  operation="sendItinerary",
  variable="itinerary"
  createInstance="yes"/>
```
  - each process must have at least one start activity as an initial activity
- Process termination
  - process-level activity completes successfully
  - fault "arrives" at the process level (handled or not)
  - terminate activity is invoked

## BPEL Long-Running (Business) Transactions (LRTs)

- Define fault handling and compensation in an application-specific manner
  - Explicitly specified as part of the business protocol
    - E.g., order of compensation steps may be different from reverse order of completion
- LRT within single, local business process, i.e., no support for LRT that spans
  - Distributed business process
  - Multiple vendors or platforms
- -> WS-Transaction specification
  - Business Activities
  - Protocol Framework can be used to model the fault and compensation relationships between a scope and its enclosing scopes

## WS-Transaction – Business Activities

---

- Characteristics
  - Usually long-running
    - Responding to a request may take a long time
  - May consume lots of resources perform a lot of work
    - Loss of state of business activity cannot be tolerated
    - Forward recovery
- Design points
  - State transitions need to be reliably recorded
  - All request messages are acknowledged
    - Detect problems early
  - Response to a request is a separate operation
    - Not the output of the request
    - Avoid problems with timeouts of message I/O implementations

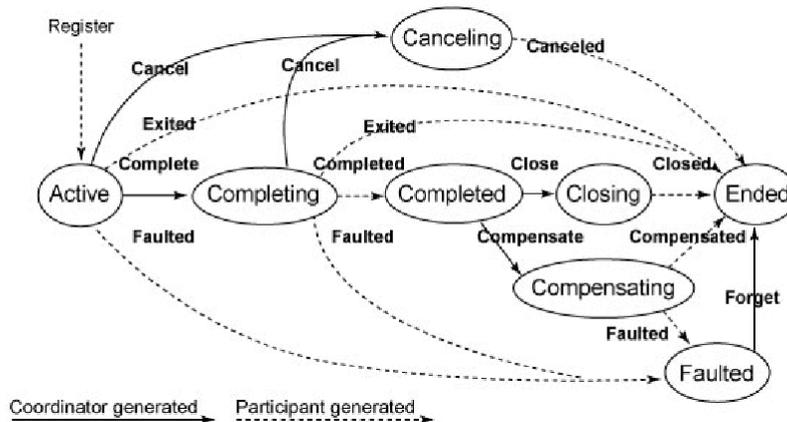

## Business Activity (cont.)

---

- Business Activity (BA) coordination type
  - Create business activity, propagate coordination context
  - Interpose a coordinator as a subordinate
  - Create business scopes (see BPEL)
    - Can be nested
  - Register for participation in BA
    - BusinessAgreement protocol
      - Nested scope participant registers with parent scope coordinator
      - Parent scope can manage it
      - Nested scope must know when it has completed all the work for a business activity
    - BusinessAgreementWithComplete protocol
      - Nested scope relies on parent to tell it when it has received all requests for work in the business activity

## Business Agreement Protocol

- BusinessAgreementWithComplete – State Diagram

## Business Agreement Protocol (cont.)

- Parent sends application message to a child
  - Contains a business CoordinationContext
- Child registers with parent as participant of the business activity (Active state)
- Parent tells child when it has received all requests by sending the complete message (Completing state)
- Child finishes
  - Case 1: no more participation required (read-only, irreversible, ...)
    - Child sends exit message (Ended state)
  - Case 2: continue participation
    - Completed: requires ability to compensate completed tasks
    - Child lives on until parent sends close or compensate message
  - Case 3: child fails while active (or compensating)
    - Send faulted message to parent
    - Parent replies with forget message
- Parent tells child to cancel
  - Child needs to abandon its work in "some appropriate way"
